Hem provat amb diferents valors de N (número de descriptors de fourier) per representar els vectors de característiques de les imatges. Amb cada un d'aquests hem entrenat models amb els diferents clasificadors (Tree, SVM i KNN) que hem vist a classe per veure quins donen millors resultats en cada cas.

Podem concloure que hi ha un clar compromís entre la quantitat de descriptors que utilitzem i els mètodes empresos. En augmentar el número de descriptors som capaços de diferenciar fulles que amb menys

descriptors s'assemblen massa, però en contrapunt l'augment excessiu del nombre de descriptors augmenta també la complexitat dels models, fent que alguns tendeixin a funcionar pitjor.

A més, si mirem els diferents scatter plots en dues dimensions, observem que on es produeix una major proximitat és entre la població de Faig i el Roure. Pensem que això és degut a que a grans rasgos, les fullen tenen una forma més semblant que no pas el Erable, que té una fulla amb una forma molt més distinguida.

Seguint amb aquesta línia, si observem la matriu de confusió del millor cas trobat (KNN amb 10 descriptors), efectivament el error es troba entre el Faig i el Roure.

D'aqui podem extreure que realment el que defineix la veritable forma de la fulla de l'arbre són els primers descriptors, ja que són els que defineixen els grans rasgos de la fulla.
